Abstract. Different miRNAs are involved in the life cycles of Schistosoma japonicum. The aim of this study was to examine the expression profile of miRNAs in individual S. japonicum of different sex before and after pairing (18 and 24 dpi). The majority of differential expressed miRNAs were highly abundant at 14 dpi, except for sja-miR-125b and sja-miR-3505, in both male and female. Moreover, it was estimated that sja-miR-125b and sja-miR-3505 might be related to laying eggs. sja-miR-2a-5p and sja-miR-3484-5p were expressed at 14 dpi in males and were significantly clustered in DNA topoisomerase III, Rap guanine nucleotide exchange factor 1 and L-serine/L-threonine ammonia-lyase. Target genes of sja-miR-2d-5p, sja-miR-31-5p and sja-miR-125a, which were expressed at 14 dpi in males but particularly females, were clustered in kelch-like protein 12, fructose-bisphosphate aldolase, class I, and heat shock protein 90 kDa beta. Predicted target genes of sja-miR-3483-3p (expressed at 28 dpi in females but not in males) were clustered in 26S proteasome regulatory subunit N1, ATPdependent RNA helicase DDX17. Predicted target genes of sja-miR-219-5p, which were differentially expressed at 28 dpi in females but particularly males, were clustered in DNA excision repair protein ERCC-6, protein phosphatase 1D, and ATPase family AAA domaincontaining protein 3A/B. Moreover, at 28 dpi, eight miRNAs were significantly up-regulated in females compared to males. The predicted target genes of these miRNAs were significantly clustered in heat shock protein 90 kDa beta, 26S proteasome regulatory subunit N1, and protein arginine N-methyltransferase 1. To sum up, differentially expressed miRNAs may have an essential role and provide necessary information on clarifying this trematode's growth, development, maturation, and infection ability to mammalian hosts in its complex life cycle, and may be helpful for developing new drug targets and vaccine candidates for schistosomiasis.

BACKGROUND

Schistosomiasis, which is caused by the genus *Schistosoma*, is one of the most serious and debilitating parasitic diseases worldwide (Song *et al.*, 2016). It has been reported that approximately 250 million

people in 78 countries endemic with this disease, while nearly 800 million are at the risk of being infected (Gray et al., 2010; The Carter Center, 2014; WHO, 2016). In China, Schiatosomiasis japonica represents a serious public health problem (Li et al., 2014; Song et al., 2016; Sun et al., 2017).

Currently, vaccines for schistosomiasis prevention are not available (Tebeje et al., 2016), and the only useful drug, i.e., praziquantel has an essential the role in treatment of schistosomiasis (Siqueira et al., 2017). However, the drug is ineffective against young worms (Wang et al., 2012). The life cycle of S. japonicum is complicated, with males and females pairing and eventually developing into adult worms in hosts. Given this condition, S. japonicum goes through remarkable morphological and molecular changes throughout its life cycle (Walker et al., 2011; Mourão et al., 2012; Sun et al., 2013). Previous studies have relied on genomic analysis technology to explain biology of S. japonicum and its interactions with hosts (S. japonicum Genome Sequencing and Functional Analysis Consortium, 2009), thus increasing our knowledge of microRNAs (miRNAs) and their evolutionary characteristics, developmental genetic switches, and novel biomarkers for S. japonicum. Consequently, a deeper understanding of the mechanisms of schistosome development and the pathogenesis of schistosomiasis may help developing novel strategies to control this disease.

Currently, different schistosome life cycle stages have been associated with different categories of miRNAs, suggesting that miRNAs may be involved in the regulation of development (Xue et al., 2008; Huang et al., 2009; Chen et al., 2010; Hao et al., 2010; Cai et al., 2011). Several lines of evidence have also indirectly implied that miRNAs may regulate the pathogenic schistosomiasis (Cheng et al., 2013). During the development of S. japonicum, males and females begin to pair approximately 14 days post-infection (14 dpi), and the female begins to lay eggs approximately 28 days post-infection (28 dpi) (He et al., 1980). Moreover, Sun et al. (2014) have reported a total of 2258 miRNAs identified in S. japonicum collected from single and doublesex infected mice; however, the authors did not provide information about the individual miRNAs before and after pairing (female at 14 dpi and 28 dpi, male at 14 dpi and 28 dpi).

In this study, the expression profiles of miRNAs in individual *S. japonicum* of different sex before and after pairing (18 dpi and 24 dpi) were investigated. Moreover, based on the analysis of the predicted targets, the different and specific functional requirements before and after pairing were determined based on the novel miRNA profiles.

MATERIAL AND METHODS

Parasites

Cercariae of *S. japonicum* were collected from the lab-infected snail *O. hupensis hupensis*, as well as hatched miracidia provided by the National Institute of Parasitic Disease, Chinese Center for Disease Control and Prevention (NIPD). Hepatic schistosomula were isolated from the portal system and from mesenteric veins of infected mice at 14 dpi. Adult worms of *S. japonicum* were isolated from the hepatic portal system and mesenteric veins of infected mice at 28 dpi. In addition, male and female adult worms were manually separated under a light microscope.

All animals were handled in strict accordance with the guidelines defined by the relevant national and/or local animal welfare bodies, and all animal experiments were approved by the ethics committee of NIPD (No. IPD-2018-16).

RNA isolation

According to the manufacturer's protocol, total RNAs from samples in female and male *S. japonicum* (schistosomulum and adult worm) at 14 dpi and 28 dpi were extracted using Trizol reagent (Invitrogen, Carlsbad, CA). RNA concentration and purity were photometrically measured at 260 nm and 280 nm using a NanoDrop ND-1000 spectrophotometer (Nanodrop Technologies, Wilmington, DE) and Agilent 2100 Bioanalyzer (Agilent Technologies, Palo Alto, CA). The extracted RNA samples were then stored at -80°C.

Small RNA isolation and library preparation

The cloning and analysis of small RNAs were performed according to the previous description (Ai et al., 2012; Xu et al., 2012). A 10 µg total RNA was separated by using a Novex 15% TBE-Urea gel (Invitrogen Co. Ltd). Then, 18-30 nt RNA was purified and the 5' and 3' adaptors (Illumina) were added to each end of the fragments. After each adaptor ligation, the small RNA was purified by using 6% TBE PAGE gel. Complementary DNA (cDNA) was obtained by a reverse transcription PCR (RT-PCR) kit (Invitrogen) for reverse transcription. Finally, the RT-PCR product was purified by using a 6% TBE PAGE gel (Invitrogen) and sequenced with an Illumina-Solexa sequencer. Image and signal processing was completed using Solexa Genome Analysis System (Illumina) A file containing the trace, "base-calling" and quality score data were generated for subsequent bioinformatics analysis.

Identification of non-coding RNA

Clean reads were analyzed as previously described (Xu et al., 2010). Firstly, in order to obtain clean reads, adaptors and low-quality sequences were trimmed from the raw data file, as well as reads smaller than 18 nt were removed. Then, the clean reads were searched against GenBank and Rfam database (version 10.1) to remove noncoding RNAs (rRNA, tRNA, snRNA, snoRNA) and other ncRNAs (Gardner et al., 2011). Repetitive sequences in the clean reads were eliminated by Repeat Masker (Bergman & Quesneville, 2007) (http://www. repeatmasker.org). The Sanger miRBase (Kozomara A & Griffiths-Jones, 2011) (version 16.0) was used to identify conserved miRNAs (Mount, 2007). The same miRNA family was judged according to reads showing high similarity to conserved miRNAs from other organisms with mismatches ≤ 2 (Wei et al., 2009). The expression and coding characters of miRNAs were statistically analyzed by family distribution and nucleotide bias. "Unannotated" reads were those, which could not be matched using any of the databases. The genome of S. japonicum (http://

lifecenter.sgst.cn/schistosoma/cn) was used as the reference genome for short read alignment using the program Short Oligonucleotide Analysis Package (SOAP) (SOAP, http://soap.genomics.org.cn). The prediction of novel miRNAs was analyzed by Mfold (Zuker, 2008) and then evaluated with MirCheck (http://web.wi.mit.edu/bartel/pub/software.html). The free energy hybridization threshold of a stem-loop hairpin was set lower than -18 kcal/mol.

Target prediction and function analysis

Algorithms Miranda was used to understand the molecular function of differentially expressed miRNAs. Moreover, TargetScan (Lewis *et al.*, 2003) was used to get the putative target sites of miRNA candidates. The result of Miranda was filtered using the Energy of miRNA_target sites: -20, Score of miRNA_target sites: 150. Sequences predicted by both software were considered as miRNA targets.

To better understand miRNA target function and classification, all predicted target proteins with an E value of 1e-5 were identified by BLASTX searching against the Interpro and KEGG database (version 76). The best hits were used to validate the target gene function and metabolic pathway regulated by miRNAs. We also established the biological process, cellular component, and molecular function of target genes using the Interpro database the same way as we used the GO database.

Analysis of miRNA expression

In order to analyze novel miRNA expression at 14 dpi and 28 dpi of *S. japonicum*, RT-PCR with SYBR Green (TOYOBO) was used. RT-PCR was performed using an ABI PRISM® 7300 Sequence Detection System and SYBR Green PCR Master Mix (TOYOBO) in a 20 µl reaction. The PCR mix contained 5 µl cDNA for each miRNA (in 1: 20 dilution), 5 µM forward and reverse primers, and 10 µl 2× SYBR Green PCR Master Mix. The *S. japonicum* 18S rRNA gene (GenBank accession number L06668) was used as the endogenous control. The primer pairs for the RT-PCR are shown in Table 1. The PCR conditions were set at 95°C 10 min, followed

by 40 cycles of 95°C for 15s, 65°C for 30s, and 72°C for 30s. The threshold cycle (Ct) was defined as the cycle number at which the fluorescence intensity passed a predetermined threshold value.

Confirmation of miRNA expression by the reverse transcriptase-polymerase chain reaction

To confirm the miRNA differential expressions at 14 dpi and 28 dpi of S. japonicum, stem-loop real-time reverse transcriptase-polymerase chain reaction (RT-PCR) with SYBR Green was applied. Real-time quantitative PCR was performed using an ABI PRISM® 7300 Sequence Detection System and SYBR Green PCR Master Mix (TOYOBO) in a 20 µl reaction. The PCR mix contained 5 µl cDNA for each miRNA (in 1: 20 dilution), 5 µM forward and reverse primers, 10 µl 2× SYBR Green PCR Master Mix. The S. japonicum 18S rRNA gene (GenBank accession number L06668) was served as the endogenous control. The primers are shown in Table 1. The PCR recycle conditions were set at 95°C 6 min, followed by 50 cycles of 95°C for 10s, 55°C for 10s, and 72°C for 30 s. The threshold cycle (Ct) was defined as the cycle number at which the fluorescence intensity passed a predetermined threshold value.

Statistical analysis

At least three independent experiments were performed. Results were presented as mean ± standard deviation. One-way ANOVA

and Student's t-test were used to perform statistical analyses. A value of P < 0.05 was considered statistically significant.

RESULTS

Profile character of short RNAs from male and female Schistosomulum (14 dpi)

Totally, 32,820,190 and 33,445,677 reads were obtained with Solexa deep sequencing from the female and the male samples of schistosomulum (14 dpi), respectively. After filtering low-quality tags, including 52 and 32 adaptors and contamination formed by adaptor-adaptor ligation, a total of 32,047,967 and 32,302,846 high-quality reads were obtained. Length distribution analysis showed that most reads were distributed among 20-23 nt in both genders. The highest percentage was 29.17% with reads that were 20 nt long, which was followed by 23.08% of 23 nt reads in male (Fig. 1A), and 27.56% with 22 nt long reads, followed by 26.29% of 20 nt reads in female (Fig.1B).

Among the clean reads, 2.59% and 2% were identified as noncoding sRNA, including tRNA, rRNA, siRNA, snRNA and snoRNA (Table 2) in male and female, respectively. Allowing the maximum mismatches of 2 nt, 4,155 (0.48%) tRNAs, 15,905 (1.83%) rRNAs, 241 (0.03%) snoRNAs, and 2,156 (0.25%) snRNA were recovered in Unique sRNAs of the male. In addition, 3,527 (0.42%) tRNAs, 11,068 (1.33%) rRNAs, 188 (0.02%) snoRNAs, and 1,935 (0.23%) snRNA were recovered in

Unique sRNAs of the female. Except for the ncRNA mentioned above, 617,848 (71.22%) and 610,420 (73.43%) of total reads had no match to the public database and were marked as un-annotated reads (Table 2).

The level of the total percentage of ncRNA repressed in the schistosomulum of different sex (14 dpi) showed the following results: in males, 20,064,794 (67.18%%) sequences were perfectly mapped to the *S. japonicum* genome, which included 293,674 (33.85%) unique sequences; in females, there were 19,615,952 (66.02%) sRNAs mapping to the target genome, which contained 259,398 (31.2%%) unique sequences.

Profile character of short RNAs from male and female adult worm of S. japonicum (28 dpi)

Totally, 31,842,941 and 35,875,743 reads were obtained with solexa deep sequencing from the male and the female adult samples of *S. japonicum* (28 dpi), respectively. After

filtering low-quality tags, including 52 and 32 adaptors and contamination formed by adaptor-adaptor ligation, a total of 31,636,846 and 35,680,733 high-quality reads were obtained. Length distribution analysis showed that most reads were distributed among 20-23 nt in both genders. The highest percentage was 42.69% with reads of 22 nt long and followed by 18.12% of 21 nt reads in male (Fig. 2A), and it was 36.10% with reads of 22 nt long and followed by 21.40% of 20 nt reads in female (Fig. 2B).

Among the clean reads, 5.28% and 2.71% were identified as noncoding sRNA, including tRNA, rRNA, siRNA, snRNA and snoRNA (Table 3) in male and female, respectively. Allowing the maximum mismatches of 2 nt, 6,358 (1.21%) tRNAs, 19,130 (3.65%) rRNAs, 174 (0.03%) snoRNAs, and 2,025 (0.39%) snRNA were recovered in Unique sRNAs of the male. In addition, 5,403 (0.63%) tRNAs, 15,744 (1.82%) rRNAs, 168 (0.02%) snoRNAs, and 2,072 (0.24%) snRNA were recovered in

Unique sRNAs of the female. Except for the ncRNA mentioned above, 389,392 (74.3%) and 836,4783 (41.63%) of total reads had no match to the public database and were marked as un-annotated reads (Table 3).

The level of the total percentage of ncRNA repressed in different gender of adult *S. japonicum* (28 dpi) showed the following results: in males, 19,682,739 (72.5%) sequences were perfectly mapped to the *S. japonicum* genome, which included 143,968 (27.47%) unique sequences; in females, there were 22,860,844 (70.55%) sRNAs mapping to the target genome, which contained 254,308 (29.43%) unique sequences.

Common and specific short RNAs sequences in schistosomulum (14 dpi) and adult worm of *S. japonicum* (28 dpi)

Among the high-quality reads, 94.89%, 90.62%, 96.90%, and 91.56% of the total reads were shared by females at 14 dpi and 28 dpi, males at 14 dpi and 28 dpi, males at 14 dpi and females at 14 dpi, and females and males at 28 dpi, respectively (Table 4). In the comparison between females at 14 dpi and 28 dpi, there were 1.39 million (2.25%) and 1.77 million (2.86%) specific sRNAs expressed, respectively. Meanwhile, the comparison between males at 14 dpi and 28 dpi, males and females at 14 dpi, as well as females and males at 28 dpi, the specific

sRNAs in each sample successively was 3.20 (5.61%), 2.15 (3.77%), 0.98 (1.65%), 0.86 (1.45%), 2.06 (4.98%) and 2.97 (3.45%) million.

Known microRNA in schistosomulum (14 dpi) and adult worm of S. japonicum (28 dpi)

The known miRNAs expressions in schistosomulum (14 dpi) and adult worm of *S. japonicum* (28 dpi) were shown in Table 5. There were 30, 31, 25, and 27 known miRNAs in males and females at 14 dpi, and in males and females at 28 dpi, respectively. The number of miRNA precursors was 51, 51, 45, and 49 in each sample, respectively. Moreover, there was no miRNA star (miRNA*) found in the above four specimens (Table 5).

Novel miRNA precursor candidates of schistosomulum (14 dpi) and adult worm of *S. japonicum* (28 dpi)

The total number of novel miRNA precursor candidates of shistosomulum (14 dpi) and adult worm of *S. japonicum* (28 dpi) were 47477, 58541, 22617 and 33979 (in males at 14 dpi, females at 14 dpi, females and males at 28 dpi), respectively (Table 4). Moreover, the number of unique miRNA candidates were 464, 480, 454, and 336 in males at 14 dpi, females at 14 dpi, females at 14 dpi, females at 28 dpi), respectively (Table 6).

SJ28Female	454	22617
SJ28Male	336	33979

Differential expression analysis of schistosomulum (14 dpi) and adult worm of *S. japonicum* (28 dpi)

There were 5 and 9 significantly differentially expressed miRNAs between mals and females at 14 dpi and 28 dpi, respectively. At 14 dpi, sja-miR-2a-5p and sja-miR-3484-5p were expressed only in male, while three miRNAs (sja-miR-2d-5p, sja-miR-31-5p and sja-miR-125a) showed high expression in females (Table 7). In females and males at 28 dpi male, except for sja-miR-219, other eight miRNAs (sja-miR-2c-5p, sja-miR-3483-3p, sja-miR-3489, sja-miR-3492, sja-miR-3495, sja-miR-3499, sja-miR-3502, and sja-miR-3505) were highly expressed in females, and 9 miRNAs were differentially compared with those at 14 dpi.

Compared with both females and males at 28 dpi, the majority of differential expressed miRNAs were highly abundant at 14 dpi, except for sja-miR-125b and sja-miR-3505, which may be related to laying eggs process. These data suggested that more miRNAs have been actively expressed at 14 dpi in both male and female (Mark: begin to paired). In addition, there were 3 femalebiased expressions and 15 male-biased expressions in miRNAs at 14 dpi and 28 dpi (Table 7 and Table 8). We found that sja-let-7 was highly-expressed at 14 dpi in both males and females. Moreover, sja-bantam was expressed at different stages in males and females; its highest expression was observed at 28dpi in females.

Schistosomulum and adult worm of S. japonicum genes targeted by S. japonicum miRNAs

The application of KEGG pathway analysis was used to investigate the characteristics

of the biochemical and metabolic processes involved in schistosomulum and adult worm of S. japonicum genes targeted by S. *japonicum* miRNAs. There was a significant difference in the expression of miRNAs, probably due to the function of sexual differentiation. We found the predicted target genes of sja-miR-2a-5p and sja-miR-3484-5p, which were expressed at 14 dpi in males and were clustered in DNA topoisomerase III, Rap guanine nucleotide exchange factor 1 and L-serine/L-threonine ammonia-lyase. Target genes of sja-miR-2d-5p, sja-miR-31-5p and sja-miR-125a, which were expressed at 14 dpi in male and female (mainly females) were clustered in kelch-like protein 12, fructosebisphosphate aldolase, class I, and heat shock protein 90kDa beta. Predicted target genes of sja-miR-3483-3p (expressed at 28dpi in females without in the 28 dpi male) were clustered in 26S proteasome regulatory subunit N1, ATP-dependent RNA helicase DDX17. Predicted target genes of sja-miR-219-5p, which were differentially expressed at 28 dpi in male and female (mainly males) were clustered in DNA excision repair protein ERCC-6, protein phosphatase 1D, and ATPase family AAA domain-containing protein 3A/ B. At 28 dpi, eight miRNAs were significantly up-regulated in females compared to males, and the predicted target genes of these miRNAs were significantly clustered in heat shock protein 90kDa beta, 26S proteasome regulatory subunit N1, and protein arginine N-methyltransferase 1.

Predicted target genes of these miRNAs, which revealed significantly high expression in females at both 14 dpi and 28 dpi were clustered in heat shock protein 90kDa beta (HSP90).

Based on the sequence similarity, clean reads but not the ncRNA or repeat sequences were blasted against known mature miRNAs dataset of *S. japonicum* in the public database of miRBase (Release 12.0) with the BLAST software (Altschul *et al.*, 1990). Two co-expression and two differential expression miRNAs were identified. To verify the results of RNA-seq, the modified stem-loop RT-PCR was performed to examine the miRNA sjamiR-125b (the highest co-expression of female and male in 14 days), sja-miR-10-5p

(the highest co-expression of female and male in 28 days), sja-miR-36-3p (the highest differential expression of female and male in 14 days), as well as sja-miR-3505 (the highest differential expression of female and male in 28 days). The sequences, as well as the melt

curves of the four miRNAs, are presented in Table 9 and Figure 3. The novel miRNAs identified in the present study may clarify the development of *S. japonicum*, thus furthering the understanding of the biology of this trematode.

Table 9. Sequences in Real-time quantitative PCR verification of co-expression and differential miRNA in male and female adult worm of Schistosomulum and $Schistosoma\ japonicum$

miRNA	Sequence	Expression stage
sja-miR-125b	TCCCTGAGACTGATAATTGC	the highest co-expression of female and male in 14 days
sja-miR-10-5p	AACCCTGTAGACCCGAGTTT	the highest co-expression of female and male in 28 days
sja-miR-36-3p	CACCGGGTAGACATTCATTCGC	the highest differential expression of female and male in 14 days
sja-miR-3505	TGACTGTCTGGACTCAGTAGCT	the highest differential expression of female and male in 28 days

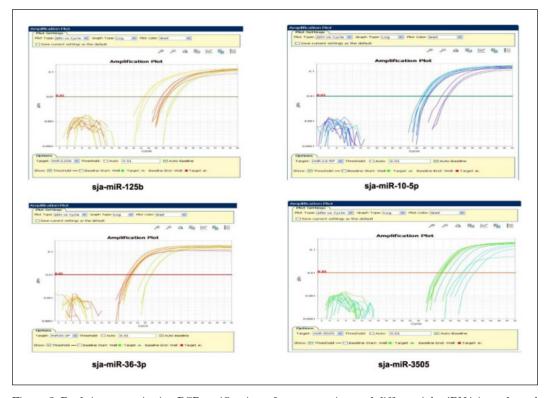

Figure 3. Real-time quantitative PCR verification of co-expression and differential miRNA in male and female adult worm of Schistosomulum and *Schistosoma japonicum*. Melt curves of four miRNAs and endogenous control (18S) is shown.

DISCUSSION

MicroRNAs are a class of small non-coding RNAs that have an important role in the transcriptional and post-transcriptional regulation of genes in both plants and animals (Liu et al., 2017; Masuda et al., 2017; Zhao et al., 2018). Over the last decade, an increasing number of miRNAs have been identified in S. japonicum, some of which regulate cellular differentiation, sexual maturation and metabolism of the trematode (Cai et al., 2011, 2013; Sun et al., 2014; Zhu et al., 2016)

During the development of *S. japonicum*, the sexual differentiation starts approximately 14 dpi infection, while egg-laying starts approximately 28 days post-infection (He & Yang, 1980). In terms of the published criteria for distinguishing bilaterian miRNAs from other types of small RNAs (Ruby *et al.*, 2006, 2007; Grimson *et al.*, 2008), it can provide insight into the mechanism underlying *S. japonicum* development, differentiation and maturation by comparing the miRNA profiles in female and male worms at 14 dpi and 28 dpi.

In this study, we examined the expression profile of miRNAs in individual S. japonicum of different sex before and after pairing (18 and 24 dpi). The majority of differential expressed miRNAs were highly abundant at 14 dpi, except for sja-miR-125b and sja-miR-3505, in both male and female (Mark: begin to be paired). Moreover, it was estimated that sja-miR-125b and sja-miR-3505 might be related to laying eggs. Besides, we found three female-biased expressions and 15 male-biased expressions in miRNAs at 14 dpi and 28 dpi; the function of 3 female-biased expressed miRNA was related to eggs laying, while 15 male-biased expressions were associated with sexual maturity.

In previous studies, let-7 has shown to be essential for the proliferation, differentiation, and apoptosis in cells (Crippa *et al.*, 2012; Shimono *et al.*, 2015; Jin *et al.*, 2016). Studies suggested that sja-let-7 take part in the transformation from miracidium to sporocyst in the snail intermediate host (Huang *et al.*, 2009). Moreover, sja-let-7 participates in chromosome transmission fidelity protein 18, large subunit ribosomal protein L21e and

N-acetyltransferase 10 (Sun *et al.*, 2014). In this study, we found that sja-let-7 was highly-expressed at 14 dpi in both males and females, which suggested that this miRNA has an important role in sexual maturation of *S. japonicum*.

Bantam are known as regulators for both proliferation and apoptosis that target the proapoptotic gene hid (Banerjee *et al.*, 2017; Wu *et al.*, 2017; Brennecke *et al.*, 2003). Moreover, predicted target genes of sjabantam participate in ATP-dependent RNA helicase DDX17, ATP-dependent DNA helicase PIF1 and chromodomain-helicase-DNA-binding protein 7 (Sun *et al.*, 2015). In this study, sja-bantam was expressed at different stages in males and females. At the same time, the highest expression levels were observed at 28 dpi in females as the report description on the function in ovary development (Zhu *et al.*, 2016).

Using a KEGG pathway analysis, we found a significant difference in the expression of miRNAs. We found that the predicted target genes of sja-miR-2a-5p and sja-miR-3484-5p, which were expressed at 14 dpi in males, were significantly clustered in DNA topoisomerase III, Rap guanine nucleotide exchange factor 1 and L-serine/Lthreonine ammonia-lyase. Target genes of sja-miR-2d-5p, sja-miR-31-5p and sja-miR-125a, which were expressed at 14 dpi in males and particularly females, were clustered in kelch-like protein 12, fructosebisphosphate aldolase, class I, and heat shock protein 90kDa beta. Liu et al. (2009) have reported that HSP90 was related to reproductive development. Predicted target genes of sja-miR-3483-3p (expressed at 28 dpi in female without in the 28 dpi male), were significantly clustered in 26S proteasome regulatory subunit N1, ATP-dependent RNA helicase DDX17. Predicted target genes of sja-miR-219-5p, which were differentially expressed at 28 dpi in females and particularly males, were clustered in DNA excision repair protein ERCC-6, protein phosphatase 1D, and ATPase family AAA domain-containing protein 3A/B. At 28 dpi, eight miRNAs were significantly up-regulated in females compared to males, and the predicted target genes of these miRNAs were

significantly clustered in heat shock protein 90 kDa beta, 26S proteasome regulatory subunit N1, and protein arginine N-methyltransferase 1.

CONCLUSIONS

The miRNAs research on *S. japonicum* may have an essential role in clarifying this trematode's growth, development, maturation and infection ability to mammalian hosts in its complex life cycle. These data may be helpful for developing new drug targets and vaccine candidates for schistosomiasis.

Conflicts of interest

The authors declare no conflicts of interest with regards to this study or the manuscript prepared for publication.

Acknowledgments.
